Dr. Muir of Dalhousie University in Canada, mentions the following in her review:\textsuperscript{[i]}: "neurologic problems ranging from headache to paralysis" and she includes adhesive arachnoiditis in her list.

SHORT-TERM COMPLICATIONS: (\textsuperscript{[ii]})

- Post dural puncture headache (commonest)
- Total spinal anaesthesia
- Meningitis (infecitive or chemical)
- Extradural haematoma
- Extradural abscess
- Anterior spinal artery syndrome (paraplegia)
- Intravascular injection
- Cauda equina syndrome (CES)
- Transient radicular irritation (TRI)
- Cranial nerve lesions/Horner's syndrome (v. rare)

Hampl et al (\textsuperscript{[iii]}) suggested that transient neurologic symptoms are "common after spinal anesthesia" and may occur in up to "one third of the patients receiving 5% lidocaine."\textsuperscript{[iv]}

Dahlgren wrote about Transient Radicular Irritation (TRI) having an incidence of 15-37% in those patients receiving lidocaine, procaine and mepivicaine (but not bupivicaine). He ascribes the symptoms to hemolyzed blood in the subarachnoid space.
